## GENERAL DESCRIPTION (Refer to Figure 3)

### RECEIVER SECTION

An input signal sent from the antenna is applied to the 1st-mixer (transistor Q2) via the RF amplifier (transistor Q1). Meanwhile, an oscillator signal delivered from the P.L.L. synthesizer is applied to the base of the transistor Q2 (1st-mixer) via the buffer circuit (transistor Q202). In this stage the above-mentioned input signal is converted to 1st-IF signal of 10.695 MHz. This 1st-IF (10.695MHz) signal is supplied to the base of the transistor Q3 (2nd-mixer) through the transformers T3 and T4. Also to this transistor Q3 is supplied an oscillator signal (11.150MHz) from the transistor Q6, in which the signal is converted to 2nd-IF signal of 455kHz. The 2nd-IF (455 kHz) signal is amplified by the 2nd-IF amplifier (transistors Q4 and Q5) and detected by the diode D2. The output signal thus detected is applied to the terminal ⑥ of the integrated circuit IC-101 through the volume control (R925), amplified by the driver circuit and audio power amplifier circuit inside the IC-101 and finally applied to the speaker via the transformer T101.

### TRANSMITTER SECTION

An audio signal sent from the microphone is applied to the terminal ⑥ of the integrated circuit IC 101 so that it be audio-amplified and then applied to the final-stage transistor Q304 and drive-stage transistor Q303 via the transformer T101. Meanwhile, a carrier signal synthesized by the P.L.L. synthesizer circuit is amplified by the 27MHz amplifier (transistors Q301 and Q302) and applied to the final-stage transistor Q304 through the drive-stage transistor Q303, in which it is modulated together with the aforesaid audio signal and finally transmitted through the antenna.

## DESCRIPTION OF PHASE-LOCKED-LOOP (P.L.L.) CIRCUIT (Refer to Figure 2)

### 1) What is P.L.L. ?

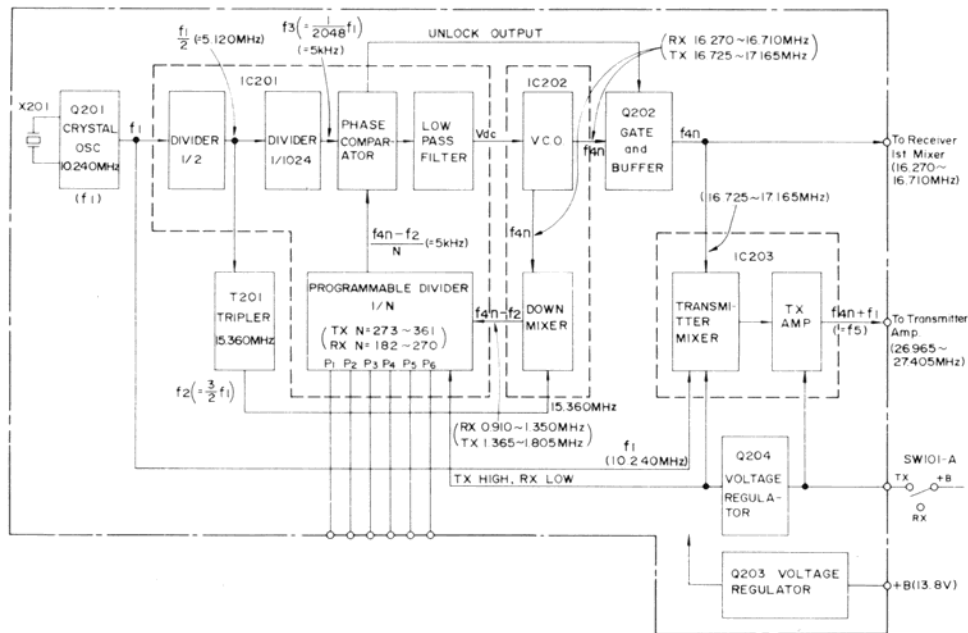

P.L.L. is abbreviation of Phase-Locked-Loop which synchronizes with frequency and phase of the stable standard input (crystal oscillation) given from the outside, namely working not only as automatic frequency control but also as automatic phase control.

The P.L.L. is now used to realize a synthesizer. Consisting of one crystal, the synthesizer serves as an oscillator to oscillate step by step (5kHz) in the receiver section range of 16.270MHz to 16.710MHz and the transmitter section range of 16.725 MHz to 17.165MHz.

Therefore, this synthesizer can be said to be on the same level in the connection with the accuracy and stability of oscillation as the crystal oscillator.

### 2) Frequency Synthesizer

The frequencies for both transmitter and receiver are synthesized by one crystal controlled oscillator and the Phase-Locked-Loop (or P.L.L.) consisting of eight basic building blocks: the divider (1/2) IC201, the divider (1/1024) IC201, the phase detector (phase comparator) IC201, the low-pass filter IC201, the voltage controlled oscillator (or V.C.O.) IC202, the down mixer IC202, the programmable divider IC201 and the tripler T201 as shown in Figure 2.

**Figure 2 P.L.L. CIRCUIT FREQUENCY SYNTHESIZER**

### 3) Frequency Determining (Refer to Figure 2 and Table 1)

- 1- The crystal oscillator consisting of a crystal X201 (10.240MHz) and transistor Q201 generates a basic frequency  $f_1$  (=10.240MHz).
- 2- The basic frequency  $f_1$  is applied to the fixed divided (1/2) network in the IC201 to be divided down to 5.120MHz signal (equivalent to 1/2 of the basic frequency  $f_1$ ). The 5.120MHz signal is further divided down to a 5kHz ( $f_3 = 1/2048 \cdot f_1$ ) signal by the fixed divided (1/1024) network and this frequency signal  $f_3$  (5kHz) is applied to the input of phase comparator.  
In addition to the above, the frequency signal  $f_1$  (10.240MHz) is also applied to the transmitter mixer inside the IC203 and the frequency signal  $f_1/2$  (5.120MHz) is converted to a signal  $f_2$  (15.360MHz) ( $f_2 = 3/2 \cdot f_1$ ) by the tripler network (transformer T201) and this frequency signal  $f_2$  is applied to the down mixer inside the IC202.
- 3- Frequency signal  $f_{4n}$  is the one that is generated by the voltage controlled oscillator (V.C.O.) inside the IC202 and this signal level is determined by DC voltage ( $V_{dc}$ ) coming from the IC201. This frequency signal  $f_{4n}$  is applied to the down mixer.  
The following will describe how the signal  $f_{4n}$  generated by the V.C.O. serves to make the P.L.L. (phase locked loop) circuit be locked.
- 4- The V.C.O. frequency signal  $f_{4n}$  is mixed down with the above-mentioned signal  $f_2$  (15.360MHz) by the down mixer inside the IC202, as a result of which there appears a mixed-down signal  $f_{4n} \cdot f_2$ . This frequency signal  $f_{4n} \cdot f_2$  is applied to the programmable divider inside the IC201.
- 5- The programmable divider (a portion of IC201) divides the frequency  $f_{4n} \cdot f_2$  by the frequency divider number  $N$  (Receiver 182 to 270, transmitter 273 to 361), which is programmable by the channel selector bit of IC901 connected to the terminal pins (11) to (16) of IC201. The assigned number is shown in Table 1. The output frequency  $(f_{4n} \cdot f_2) / N$  (near 5kHz) of the programmable divider is applied to another input of the phase comparator.
- 6- The phase comparator (IC201) compares the frequency  $f_3$  (=5kHz) and the other frequency  $(f_{4n} \cdot f_2) / N$  from the programmable divider and generates a DC voltage  $V_{dc}$  (voltage control signal) proportional to the phase differences of both frequencies. The signal  $V_{dc}$  moves downward when  $(f_{4n} \cdot f_2) / N$  goes higher than  $f_3$  and moves upward when  $(f_{4n} \cdot f_2) / N$  goes lower than  $f_3$ . When  $(f_{4n} \cdot f_2) / N$  equals to  $f_3$ , the  $V_{dc}$  does not move.  
The voltage signal  $V_{dc}$  from the output of phase comparator goes back to the V.C.O. (voltage controlled oscillator) IC202 via the low-pass filter. Then the closed feedback loop is established.
- 7- In this method, a closed-loop frequency-feedback system, which is so called P.L.L., is formed and the frequency  $f_{4n}$  of V.C.O. IC202 is locked.
- 8- When the P.L.L. is in lock, the two input signal frequencies to the phase comparator input are equal. Therefore the frequency  $f_{4n}$  is determined as follows:

#### The Receiver Frequency

$$f_{4n} = N \times f_3 + f_2$$

$$\text{where } f_2 = 15.360\text{MHz } (=3/2 \cdot f_1)$$

$$f_3 = 5\text{kHz } (=1/2048 \cdot f_1)$$

$$N = 182 \text{ to } 270 \dots \text{ Determined channel select bit of IC901 as shown in Table 1.}$$

For example, the frequency  $f_{4n}$  of "channel 1" is calculated as follows:

$$\begin{aligned} f_{4n} &= 182 \times 0.005 + 15.360 \text{ (MHz)} \\ &= 16.270 \text{ (MHz)} \end{aligned}$$

Namely " $N=182$ " is assigned for "channel 1". This frequency  $f_{4n}$  is applied to the first mixer Q2 of receiver and the mixer IC203 of transmitter through the buffer amplifier Q202 and the filter coils T205 and T206.

#### The Transmitter Frequency

$$(1) \quad f_{4n} = N \times f_3 + f_2$$

$$\text{where } f_2 = 15.360\text{MHz}$$

$$f_3 = 5\text{kHz}$$

$$N = 273 \text{ to } 361 \dots \text{ Determined by channel select bit of IC901 as shown Table 1.}$$

(During the transmission, switching signal becomes high level (DC) so that the frequency divider number  $N$  is changed from one to another and then the number will be applied to the programmable divider.)

For example, the frequency  $f_{4n}$  of "channel 1" is calculated as follows:

$$\begin{aligned} f_{4n} &= 273 \times 0.005 + 15.360 \text{ (MHz)} \\ &= 16.725 \text{ (MHz)} \end{aligned}$$

Namely " $N=273$ " is assigned for "channel 1".

This frequency  $f_{4n}$  is applied to the first mixer Q2 of receiver and the mixer IC203 of transmitter through the buffer amplifier Q202 and the filter coils T205 and T206.

- (2) The transmitter frequency  $f_5$  is determined by mixing the frequency  $f_{4n}$  and the frequency  $f_1$  (= 10.240MHz).

$$f_5 = f_{4n} + f_1$$

$$= N \times f_3 + f_2 + f_1$$

$$\text{where } f_1 = 10.240\text{MHz}$$

$$f_2 = 15.360\text{MHz}$$

$$f_3 = 5\text{kHz}$$

$$N = 273 \text{ to } 361$$

For example, the frequency  $f_s$  of "channel 1" is calculated as follows:

$$f_s = 273 \times 0.005 + 15.360 + 10.240 \text{ (MHz)}$$

$$= 26.965 \text{ (MHz)}$$

Table 1 shows the synthesized frequencies for each channel.

- 9- The gate and buffer circuit made of transistor Q202 works to prevent emission of unnecessary waves when the P.L.L. circuit is unlocked.
- 10- The frequency divider number  $N$  of programmable divider is decided by the value set by either of the channel selector LSI (IC904). In any of the channels, it is designed that the frequency divider number  $N_T$  at the transmission is larger than that  $N_R$  at the reception by a difference of 91.  
 $N_R = N_T - 91$

8 (27MHz Frequency Readjust)	Same as step 7.	C203	1) Set the channel to "20". 2) Readjust so that the frequency counter reads within 27.205 MHz $\pm$ 300 Hz.

## RECEIVER ALIGNMENT

STEP	CONNECTION OF MEASURING INSTRUMENT	ADJUSTMENT	PROCEDURE
1 (11.150 MHz)	Connect a frequency counter, through 5PF capacitor, to the test point <b>TP1</b> . (Base of transistor Q3)	T8	Adjust so that the frequency counter reads within 11.150 MHz $\pm$ 100 Hz. (The oscillation voltage then is about 90mV)
2 (1st-IF and 2nd-IF)	1) Connect an AC V.T.V.M. to both sides of the speaker voice coil lug. 2) Connect a signal generator, through 0.01 MFD capacitor, to the test point <b>TP2</b> (the secondary of the transformer T2). 3) Set the signal generator to 10.695 MHz, modulation 1000 Hz, 30% . NOTE: Be sure to connect the ground wire of signal generator to the ground of the antenna socket.	T3 T4 T5 T6 T7 T9	Adjust so that the AC V.T.V.M. reads the maximum.  IF waveform can be said to be best adjusted when it becomes maximum in size and its band width is the widest with the central frequency similar to that of the ceramic filter.
3 (RF)	1) Connect the AC V.T.V.M. to both sides of the speaker voice coil lug. 2) Connect the signal generator to the antenna socket. 3) Set the signal generator to 27.175 MHz (18 channel), modulation 1000 Hz, 30% .	T2 T1	1) Set the channel to "18". 2) Adjust the AC V.T.V.M. until it reads the maximum.
4 (Deepest Point of Squelch)	1) Connect a signal generator to the antenna socket, keeping the frequency of signal generator to 27.175 MHz ("18 channel") and modulation 1000Hz, 30%. 2) Connect a low-frequency wattmeter to the external speaker jack.	R43 (30K ohms -B)	1) Adjust the channel indication of the unit to "18" and set the volume control to "MAX" position. 2) Set the output level of a signal generator to "60 dB" (1000 Hz, 30%). At the time make sure the low-frequency wattmeter reads approx. 4W (maximum). 3) Next, adjust the volume control so that the low-frequency wattmeter indicates 500 mW. 4) Rotate the squelch control knob of the unit fully clockwise. 5) Adjust the semi-fixed resistor R43 so that the low-frequency output becomes 0.05W.

## TRANSMITTER AND MODULATOR ALIGNMENT

- 1- When the set is made ready for the transmitting operation, be sure to always connect the RF output power meter and 50 ohms dummy load to the external antenna socket—this should never be forgotten even if it is not noted down specifically. If otherwise, the final transistor Q304 may be damaged.
- 2- When making the connection of measuring instruments, see Figure 5.

Figure 5

STEP	CONNECTION OF MEASURING INSTRUMENT	ADJUSTMENT	PROCEDURE
1 (27 MHz Filter)	Connect the synchroscope to the test point <b>TP301</b> (Base of transistor Q302).	T301 T302	1) Set the channel to "40". 2) Adjust so that the maximum waveform (amplitude) appears on the synchroscope. 3) Set the channel to "1" and/or "40" to make sure the waveform doesn't decrease in size. 4) Loosen the core of T301 by 2 turns from a peak point where the output is maximum.
2 (Buffer)	1) Remove the plug which have been inserted in the test points <b>TP308</b> and <b>TP309</b> of the set. 2) Connect in turn DC milliammeter, through the RF rejection filter shown in Figure 6, to the test points <b>TP308</b> and <b>TP309</b> .	T303	1) Set the channel to "40". 2) Adjust so that the DC milliammeter connected to the test point <b>TP309</b> reads the maximum. (Driver current)
3 (Driver)	Same as above.	T304	Adjust so that the DC milliammeter connected to the test point <b>TP309</b> indicates the dip point. The amperage then is about 45 to 80mA.
4 (Final)	Same as step 2, and connect the RF output power meter and 50 ohms dummy load to the antenna socket.	L301	Adjust so that the DC milliammeter connected to the test point <b>TP308</b> reads 450mA ± 50mA (Final current).
5 (π-Filter)	Same as above.	L302	Adjust so that the RF output power meter reads the maximum. The reading then should not exceed 4W. (FCC Rules and Regulations Part 95, Section 95. 43.)
6	Repeat the steps 2 to 5 until the best results will be obtained.		
7 (Modulation)	1) Connect the RF output power meter, 50 ohms dummy load and synchroscope, through CM coupler, to the antenna socket. 2) Connect a audio signal generator, attenuator and AC V.T.V.M. to the microphone terminal. 3) Keep the output of audio signal generator to 1000 Hz, 700mV.	R110 (1K ohms -B)	1) Set the channel to "20". 2) Turn R110 counterclockwise until the modulation limiter circuit stops its function. 3) Make sure there appears 700mV input signal at the microphone terminal from an audio signal generator. 4) Depress the press-to-talk switch on the microphone. 5) Adjust R110 so that the modulation factor of RF output waveform appeared on the synchroscope becomes 95 to 99%(See Figure 7). 6) Set the attenuator to "-41dB" (6 mV). 7) Make sure the modulation factor of RF output waveform on a synchroscope is more than 50%.
